

My Notes About *log* of Gamma

By David Dobor

A random variable X is said to have a gamma distribution with parameters (α, β) , denoted by $\Gamma(\alpha, \beta)$, if its pdf is given by:

$$f(x) = \frac{1}{\Gamma(\alpha)} \cdot \frac{1}{\beta} \cdot \left(\frac{x}{\beta}\right)^{\alpha-1} \cdot e^{-\frac{x}{\beta}} \cdot 1_{(0,\infty)}(x) \text{ where } \alpha, \beta > 0$$

Here $\Gamma(\alpha)$ is the gamma function computed as $\int_0^\infty e^{-y} y^{\alpha-1} dy$ and $1_{(0,\infty)}(x)$ stands for the indicator function (i.e. it's value is 1 for non-negative x -es and 0 elsewhere).

Distribution of Log of Gamma

First, we are interested in the distribution of the natural logarithm of Gamma. Let $Y = \log(X)$ where $X \sim \Gamma(\alpha, \beta)$. We want the distribution of Y .

We'll use the following well known theorem about computing the density of a transform, g , of some random variable X . Loosely put, if $g(X) = Y$ and g has an *inverse*, call it $h(Y)$, then the pdf of Y is:

$$f_Y(y) = f_X(h(y)) |h'(y)|$$

So here, denoting the inverse of $Y = \log(X)$ by $h(Y)$, we have $X = h(Y) = e^Y$ and $h'(y) = e^y$. Therefore:

$$\begin{aligned} f_Y(y) &= f_X(h(y)) |h'(y)| \\ &= \frac{1}{\beta^\alpha \Gamma(\alpha)} \left(e^{\alpha(y-1)} - e^{-e^{y/\beta}} \right) |e^y| 1_{(-\infty, \infty)}(y) \\ &= \frac{1}{\beta^\alpha \Gamma(\alpha)} \left(e^{\alpha y} - e^{-e^{y/\beta}} \right) e^{-y} e^y 1_{(-\infty, \infty)}(y) \\ &= \frac{1}{\beta^\alpha \Gamma(\alpha)} e^{(\alpha y - e^{y/\beta})} 1_{(-\infty, \infty)}(y) \end{aligned}$$

This expression is a valid pdf – it integrates to 1 - and is said to have a Log-Of-Gamma pdf with parameters (α, β) .

Moments of Log Of Gamma

We now find the Moment Generating Function (MGF) of $\text{Log-Of-Gamma}(\alpha, \beta)$. By definition:

$$M_Y(t) = \int_{-\infty}^{+\infty} e^{ty} \frac{1}{\beta^\alpha \Gamma(\alpha)} e^{(\alpha y - e^{y/\beta})} dy$$

To integrate this we use an old trick: we try to leave inside the integral sign the part of the function that integrates to 1 (this is often an easily recognizeable pdf); we then pull the constants that get in the way of making this integral equal to 1 out of the integral sign. Luckily, this can be done here:

$$\begin{aligned} M_Y(t) &= \frac{1}{\beta^\alpha \Gamma(\alpha)} \int_{-\infty}^{+\infty} e^{ty} e^{(\alpha y - e^{y/\beta})} dy \\ &= \frac{1}{\beta^\alpha \Gamma(\alpha)} \int_{-\infty}^{+\infty} e^{(ty + \alpha y - e^{y/\beta})} dy \\ &= \frac{1}{\beta^\alpha \Gamma(\alpha)} \cdot \frac{\beta^{\alpha+t} \Gamma(\alpha + t)}{\beta^{\alpha+t} \Gamma(\alpha + t)} \cdot \int_{-\infty}^{+\infty} e^{(y(\alpha+t) - e^{y/\beta})} dy \\ &= \frac{\beta^{\alpha+t} \Gamma(\alpha + t)}{\beta^\alpha \Gamma(\alpha)} \cdot \int_{-\infty}^{+\infty} \frac{1}{\beta^{t+\alpha} \Gamma(\alpha + t)} e^{(y(\alpha+t) - e^{y/\beta})} dy \\ &= \frac{\beta^t \Gamma(\alpha + t)}{\Gamma(\alpha)} \end{aligned}$$

Where the last equality follows because the thing inside the integral is the Log-Of-Gamma pdf derived above and integrates to 1.

In Short:

$M_Y(t) = \frac{\beta^t \Gamma(\alpha + t)}{\Gamma(\alpha)} \quad \text{when } Y \text{ is } \text{Log-Of-Gamma}(\alpha, \beta)$
--

Cumulant Generating Function

The Cumulant Generating Function (CGF) of a random variable Y is defined as:

$$S_Y(t) = \log(M_Y(t))$$

It can be verified that:

$$\left. \frac{d}{dt} S_Y(t) \right|_{t=0} = E Y \quad \text{and} \quad \left. \frac{d^2}{dt^2} S_Y(t) \right|_{t=0} = \text{Var}(Y)$$

Expectation and Variance of Log Of Gamma

To find the expectation of `Log-Of-Gamma`, we differentiate $S_Y(t) = \log(M_Y(t))$ and evaluate the result at $t = 0$.

$$\begin{aligned}
 (S_Y(t))' &= (\log(M_Y(t)))' = \left(\log \left(\frac{\beta^t \Gamma(\alpha + t)}{\Gamma(\alpha)} \right) \right)' \\
 &= \frac{1}{\frac{\beta^t \Gamma(\alpha + t)}{\Gamma(\alpha)}} \cdot \frac{1}{\Gamma(\alpha)} \cdot (\beta^t \Gamma(\alpha + t))' \\
 &= \frac{\Gamma(\alpha)}{\beta^t \Gamma(\alpha + t)} \cdot \frac{1}{\Gamma(\alpha)} \cdot (\beta^t \log(\beta) \Gamma(\alpha + t) + \beta^t \Gamma'(\alpha + t)) \\
 &= \log(\beta) + \frac{\Gamma'(\alpha + t)}{\Gamma(\alpha + t)}
 \end{aligned}$$

The last term is the log-derivative of the Gamma function evaluated at $\alpha + t$. This log-derivative is called the digamma function and is denoted by $\psi(\cdot)$. Thus:

$$(S_Y(t))' = \log(\beta) + \psi(\alpha + t)$$

We conclude that if Y is `Log-Of-Gamma`(α, β) distributed, then its expectation is given by:

$$EY = \log(\beta) + \psi(\alpha)$$

To find the variance of Y , we look at the second derivative, $(S_Y(t))''$, and evaluate it at $t = 0$.

$$\begin{aligned}
 (S_Y(t))'' &= (\log(\beta) + \psi(\alpha + t))' \\
 &= \psi'(\alpha + t)
 \end{aligned}$$

The derivative of digamma is the so-called trigamma function:

$$Var(Y) = \psi'(\alpha) = \text{trigamma}(\alpha)$$
